The Gold Brook Covered Bridge consists of a single span support by two flanking timber Howe trusses. Each truss incorporates iron suspension rods which connect the top and bottom chords be tween the diagonal timber braces and counter braces; there are two suspension rods between adjoining sets of timber braces. The original timber deck beams have been replaced with railroad rails laid both perpendicular and parallel to the bottom chords to support the bridge floor.  The Gold Brook Bridge is 48.5 feet long at floor level and 17 feet wide; it has a 13.5-foot roadway. The wood floor consists of planks laid flat and perpendicular to the trusses. The structure rests on abutments built of irregular stone slabs laid dry.  On the exterior, the timbers bolted together to form the trusse (and side walls) of the bridge are sheathed with unpainted flus boards hung vertically. Similar siding protects the ends of the trusses immediately inside the portals. The siding stops short of the eaves to leave strip openings along the tops of the wall.  The gable ends are also sheathed with unpainted flush boards hu vertically. The portal openings have diagonal upper corners, which cover the first interior struts. The top chords project 2.5 feet beyond the gable ends to support the wide overhangs of the roof; the ends of the chords are enclosed with unpainted flush vertical boards which taper downward to meet the side walls. The medium-pitch gable roof is covered with corrugated	The Gold Brook Covered Bridge consists of a single span support by two flanking timber Howe trusses.
