___ fair	___ unexposed		

Some historic buildings are now in ruins.

Describe the present and original (if known) physical appearance

QUINCY MINE LOCATION: Situated on the Pewabic amygdaloid lode, the Quincy location stretches northeast to southwest along the brow of a long hill above the City of Hancock and Portage Lake. Parallel to the east side of U.S. Highway 41 (old Calumet Road) are the seven Quincy Mine shafts and surface works, including the Pewabic mines acquired in 1891 (North Quincy). Below the mines, spread across the hillside, are several discrete subdivisions of company housing, the earliest (Lower Pewabic) dating from 1899.

On the west side of the road, facing the highway, is a series of administrative and service buildings and managers' residences. Behind these are seven small neighborhoods of company housing, including some extant buildings from as early as the 1860s. The names of these housing clusters reflect the character of the place and make reference to the ethnic origins of the population: Limerick, Singsing, Frenchtown, Hardscrabble, Pewabic, Franklin, and Backstreet.

With a few exceptions the Quincy Development Corporation (QDC) continues to own all the lands which belonged to the Quincy Mining Company when operations ceased. Because no new developments have occurred since the mines closed, the integrity of the site as a whole is exceptionally high. There are virtually no intrusions or non-contributing structures, and modifications to housing have been minimal, since many houses even today are leased from Quincy. Others are privately owned on leased land. QDC is presently in the process of platting subdivisions to sell houses to their occupants; the land will continue to belong to the Corporation. The modern upgrading of the Calumet Road to a two-lane highway (U.S. 41) has somewhat altered the historic character of the site.

On the location itself, the integrity of feeling and association is unusually strong. Although all of the shaft-rockhouses (headframes) except No. 2 have been removed, the shafts are still evident, fenced off for safety and covered with steel grating. Some of the associated surface works have been torn down, but many structures stand, while several others remain as significant and identifiable ruins. Smokestacks from the boilerhouses punctuate the hillside, while abandoned railroad trestles and narrow gravel lanes are expressive of patterns of work and community life at the location. Apple trees, planted decades ago to improve the quality of life in an industrial setting, still line the unimproved roads and cluster around the foundations of mine buildings and miners houses, alike.

The workmanship and design of several periods of development at the site are evident, from the early vernacular Pewabic and Quincy buildings constructed of local sandstone to the classical styling of the No. 2 hoist

8. Significance

Period	Areas of Significance—Check and justify below			
___ prehistoric	___ archeology-prehistoric	___ community planning	___ landscape architecture	___ religion
___ 1400–1499	___ archeology-historic	___ conservation	___ law	___ science

X 1800–1899	___ commerce	___ exploration/settlement	___ philosophy	___ transportation
X 1900–	___ communications	X industry	___ politics/government	___ other (specify)
		___ invention		

Specific dates 1846-1931 **Builder/Architect** Quincy Mining Company

Statement of Significance (in one paragraph)

The Keweenaw Peninsula, approximately fifty miles long and fifteen miles wide, lies at the northernmost tip of Michigan as it juts out into Lake Superior. The copper range forms a narrow spine along which some four hundred copper mining companies operated between 1872 and 1920. Copper occurs in this district in fissure deposits in a pure metallic state, unalloyed with other elements. The remains of hundreds of ancient diggings, excavated by prehistoric miners, led nineteenth-century explorers to these mass copper deposits. These deposits were first mined in the early 1840s, setting off a boom which spurred settlement of Michigan's Upper Peninsula. This boom brought experienced miners from the copper mines of Cornwall, England. Then at its peak and the world leader in production, Cornwall would soon be eclipsed by Michigan.

Although the surface fissure deposits were rich, they were soon exhausted. The most productive and profitable mineral deposits of the region proved to be the amygdaloid and conglomerate lodes, located in the central portion of the copper range, which were exploited beginning in the late 1850s. In the twenty-five year period prior to the opening of the Calumet conglomerate lode the United States produced less than 6 percent of the world's copper, Michigan accounting for 74.5 percent of the U.S. total. Between 1867 and 1884, the years following the development of the conglomerate lodes, the United States increased its output to 17 percent of world copper production, Michigan accounting for 12 percent of the world total.[1]

By the mid-1880s, the western copper mines began to challenge Michigan's hegemony. In 1883 Michigan's average share of United States copper production had dropped from 80 percent to 51.6. Although the Keweenaw boom continued into the early twentieth century, its substantial contributions to the industry were superceded by the new giants of the west.[2]

A number of properties and sites related to copper mining on the Keweenaw Peninsula exist: the Cliff Mine site, which was the first of the great

Edwin Ylitalo	House #108, Sing-Sing

house, with its brick veneer, Palladian windows, and green tile roof. The housing, too, reflects the span of time and types in the history of "Old Reliable." Small, single-cell log miners' houses now covered with clapboard stand in Limerick. Examples of the slightly larger "telescope house" on mine rock foundations are also present. In Lower Pewabic a few rows of houses constructed in 1917 from plans purchased from Sears and Roebuck stand virtually unchanged. Fronting the highway in "management row," carpenter gothic, bracketed Italianate, and sandstone Romanesque stylings announce the company offices and official residences. Although a few of these buildings have been removed, the row is basically intact and in fair to excellent condition.

Two of the most significant structures bear special mention: the No. 2 shaft-rockhouse, rebuilt for the third time in 1908 over a shaft that eventually reached 9,000 feet, and the No. 2 hoist house, built in 1918 to house the largest hoisting engine in the world. Because of the preservation efforts of the Quincy Mine Hoist Association, which has a 99-year lease on these properties, both the structures and the revolutionary equipment which they house are stable and sound. The Quincy Mining Company No. 2 Hoist was designated a National Historic Mechanical Engineering Landmark in 1984 by the American Society of Mechanical Engineers. The Nordberg hoisting engine itself has been restored to mint condition for public exhibition. The Association has just completed resheathing the No. 2 shaft-rockhouse, and plans to continue restoration work on both structures.

QUINCY SMELTING WORKS

Built in 1898 on the site of the Pewabic stamp mill, the Quincy smelter juts out from the shoreline of Portage Lake on a site distinctly identifiable from its surroundings. From a vantage point across the water on the Houghton side, the smelter looks virtually as it did in 1905. To the west, Hancock is more highly developed, but the entire sweep of Quincy Hill still rises behind it--an almost bare slope, devoid of subdivisions, shopping malls, or even roads. A single road, which has linked Hancock and Torch Lake since the mining companies first erected mills along the waterfront, passes behind the smelter. Across the road a row of large, evenly spaced dwellings announces the residential district for Quincy's smelter managers and supervisors. Some of these are now privately owned.

All of the key structures which were in place in 1920 remain today, as well as many of the secondary buildings and site features. Of greatest significance are the cupola and reverberatory furnace buildings. The reverberatory building now houses melting furnaces built in the 1940s. From the melting furnace, the copper went to the refining furnace and then

to the casting plant. These works, including the 1920 Walker casting machine, are present at the site. Although equipment has been removed from many of the buildings, the heart of the smelting works remains, as do many objects of significant interpretive value, such as the 1919 Corliss-valved steam engine, slag buggies, copper molds, and ladles.

With the exception of the 1898 smelter office, which is in excellent condition with its original interior and even many furnishings in place, the structures are in fair to poor condition. Most of the buildings were constructed of local Jacobsville sandstone and are handsome and solid structures which have withstood abandonment relatively well. Roofs are beginning to decay, however, so that without preservation measures, losses will be inevitable. The cupola building has already begun to deteriorate from its damaged roof down to the upper portions of the walls. The original reverberatory furnace building has been re-roofed in recent years.

Given the otherwise exceptional integrity of the site, the condition of the buildings is a matter of concern. The Quincy Smelting Works is the only remaining smelter associated with Michigan copper mining. It may be the only essentially unaltered extant smelting complex in the U.S. which remains from the turn of the century. QDC has recently donated the smelter to Michigan Technological University in Houghton, which will eventually develop the site through The Ventures Group, the university's investment organization. (QDC is a member organization in The Ventures Group.) The University recognizes the historic value of the site. At the same time, The Ventures Group is actively involved in plans for waterfront development. As yet, no plan has been adopted for the Quincy Smelting Works.

Quincy Mining Company National Historic Landmark--Summary of Resources

In the itemized lists for each of these areas that follow:

--Hyphenated numbers are double or multiple residences and are counted as single buildings.

--Inclusive series of buildings or building sites are indicated with arrows, e.g. 132→ 135 (all). Series of buildings that are all odd-numbered or even-numbered are indicated by 201→ 221 (odd) or 200→ 220 (even).

--Many contributing sites heretofore unidentified may be presumed to exist.

--Numerous roads, railroad grades, waste rock piles, uninventoried machinery and other objects, as well as landscaping elements such as mining-era apple trees, are also contributing elements.

Michigan copper mines; the Quincy Mining Company properties, including the Franklin and Pewabic mines; the Calumet and Hecla Mining Company location and adjacent village of Red Jacket (the present Village of Calumet); and the Champion Mine of the Copper Range Company, along with its company town, Painesdale.

Of these properties, those associated with the Calumet and Hecla company and the Quincy Mining Company together represent the major elements of the Michigan copper industry: mining and mining technology, immigration and ethnic settlement, paternalism and company towns, and labor organization. The two companies represent the greatest longevity, production, technical innovation, and influence in the Michigan industry throughout its history, and for the period 1867-1882 in the copper industry nationwide.

The Quincy Mining Company represents an outstanding example of the growth and development of the United States copper industry from its earliest years through 1920. Of the numerous mining ventures spawned by the nation's first copper boom, Quincy alone survived. It was the first company to recognize the limits of fissure mining and shift to amygdaloid beds, which, with the conglomerate lodes, were the low mineral-content rock upon which the future of the district depended. The company earned the title "Old Reliable" for a fifty-four year sequence of dividends paid to its stockholders and its ability to continue mining during economically difficult times when all but the giant Calumet and Hecla had shut down.

The Quincy Mining Company made a singular contribution to the Northern effort during the Civil War. Between 1862 and 1868 Quincy ranked first nationally in copper production, supplying the raw material for brass buttons, copper canteens, bronze cannon, and naval equipment, especially copper sheathing for vessels. When the war began in 1861, Michigan produced 89.5 percent of United States copper, the Quincy mine accounting for 56 percent of that figure.[3] By 1865 Quincy was producing five times more ore than the largest-producing fissure mine. Although after 1868 Quincy could not match Calumet and Hecla's output, it remained second in the nation until the late 1880s, when Michigan lost its top rank to the western mines.[4]

[4]. Larry D. Lankton and Charles K. Hyde, Old Reliable: An Illustrated History of the Quincy Mining Company (Hancock, Michigan: Quincy Hoist Association, Inc., 1982), pp. 152-53.

The Quincy Mining Company was a leader in mining technology. Working the deepest inclines in the district, Quincy produced or adapted the specialized technology of hard-rock mining to meet the demands of the lode. As early as 1850 Quincy replaced its primitive ladders with man-engines. Shortly after the Civil War the company introduced the first use of power drills in its Pewabic mine.

Quincy was the first company to consolidate the European processes of breaking, sorting, and cleaning the rock at the spot where it was dumped from the skips. The "shaft-rockhouse", which Quincy introduced in 1873, served as a model for the Michigan copper industry.

Quincy was the first Keweenaw mine to adopt mechanized tramming, and by 1901 the company began experimenting with electric haulage. Soon the company had a stable of 15 electric locomotives in operation on the main drifts, each pulling 3 to 4 cars--with a resulting 25 percent increase in production. Six years later Quincy's engineering department devised and patented automatic side-dumping cars to eliminate the time and effort spent in uncoupling and turning the tramcars.[5]

The ability to raise the rock from underground depended upon the hoisting equipment. In this area, too, Quincy led the industry, utilizing some of the largest steam engines in the United States. In 1894 Quincy purchased a 2,500 horsepower hoist from E. P. Allis & Company of Milwaukee. The duplex cylinder engine, the biggest Allis had ever built, raised skips at 2,500 to 3,000 feet per minute.[6] In 1917 Quincy ordered its largest compound, condensing steam hoist from the Nordberg Manufacturing Company. The hoist, which operated at 3,200 feet per minute and could lift ten tons of copper rock per trip, was the largest steam hoisting engine in the world.[7] The engine with its condensing equipment remains in the No. 2 hoisthouse, which was constructed to house it.

The construction of the Quincy Smelting Works in 1898 represented a significant development in the growth and autonomy of the company. Typically in the industry, mining companies would contract with independent smelting companies to process their ore--the expense of

erecting and operating such a plant usually being too large to justify. Quincy's output at the turn of the century warranted such a facility, which was erected on Portage Lake at the foot of Quincy Hill. The two most important components were the reverberatory and cupola furnaces, which recovered copper first from the rock and then from the slag. In 1920, Quincy added a revolving Walker casting machine to mechanize the old hand ladling process. This equipment remains on site.

The social history of the Quincy mines and related communities is also important, especially in terms of ethnicity and labor relations. The mining communities of the 1860s reflected the first wave of immigrants from the 1840s: Cornish, Irish, German, a few Scandinavians, and French-Canadians who worked as timbermen and woodchoppers, but rarely in the mines. The various ethnic groups lived in distinct neighborhoods in company housing or in nearby Hancock, which was originally owned and platted by Quincy. A proliferation of churches, meeting halls, and benevolent societies reflected distinct ethnic origins. The Cornish, however, remained the dominant group through the nineteenth century, Michigan mining practices and culture being virtually transplanted from the copper and tin mines of early nineteenth-century Cornwall.

By 1905, Quincy had some 1400 employees working at the mine location. Finns by now accounted for one third of the foreign-born, with sizeable groups of Italians and Austrians among the recent immigrants. The experience of Finns and Italians at Quincy typified the experience of latecomers throughout the district: they were hired for the most laborious and low-paying jobs, so that a job hierarchy quickly developed along ethnic lines. This had a direct bearing on the deteriorating labor relations which led to the strike of 1913.

Although labor disaffection and sometimes ensuing violence were characteristic of this period nationwide, the Michigan copper district strike of 1913-1914 warrants special attention. It initiated a national response and hastened the demise of one of the strongest unions in the nation. When local members of the Western Federation of Miners called for a strike in July, 1913, Quincy's underground workers joined thousands of others throughout the Michigan district. Quincy responded to the shutdown with evictions and the importing of 1,200 strikebreakers. As the weeks passed, the mine owners showed no sign of compromise. Congress launched an investigation. State and federal governments tried to effect a

settlement. Such notables as Mother Jones, John L. Lewis, and Clarence Darrow came to the district to support labor's cause.

By the time the strike ended in an unqualified victory for the owners, the Western Federation of Miners had so depleted its resources in support of the Michigan strike that it no longer remained a viable union for its western members. Although it reorganized two years later as the International Union of Mining, Mill and Smelter workers, this labor organization, renowned for its success in organizing western miners and for its radical beginnings, never regained its former power.

The Quincy Mining Company was weakened as well. The demand for copper during World War I temporarily enabled the company to improve its position within the industry. However, finding copper ore at a reasonable cost became increasingly difficult. During the 1920s the company increased the depth of its mines and mechanized most of the operations. By 1931 the Quincy shaft No. 2 reached a depth of 9,009 feet--the deepest mine in the United States.

In 1931, the drop in copper prices during the Great Depression closed down operations. Although the company geared up again after 1937 to meet rising copper prices and the demands of World War II, its boom years were over. By 1943, Quincy opened a reclamation plant to process ore from the mill stamp sands as a supplement to waning mine productivity. In 1957 mining operations ceased, although the reclamation plant continued to produce copper for another ten years.

BOUNDARY JUSTIFICATION

The boundary here described includes the locations of mine shafts and buildings directly connected with Quincy mining operations. It encompasses part of Quincy Hill, which connects the mining area with the Quincy Smelting Works. In addition, it includes administrative and residential structures which bear witness to the various kinds of support necessary for the mining operations, including remaining neighborhoods of workers' housing that appear to possess a high degree of integrity.

BOUNDARY DESCRIPTION

Begin in the NW 1/4 of the NE 1/4 of the NE 1/4 of the NW 1/4 of Sec. 36, T55N, R34W at the south edge of Highway M-26 (Royce Road) at the point where Quincy Development Corporation (QDC) and Michigan Department of Transportation property lines meet. (See Map A)

Proceed due north across M-26 following the boundary line between the properties of L. Jokela and QDC. At the section line between Sections 36 and 25, proceed due west along the south boundary of QDC property until that line is intersected by the line forming the east boundary of the L. Jokela land and the west boundary of the QDC properties. Then proceed due north along this line to the northeast corner of the Michigan Bell tract, which point lies in the SE 1/4 of the SW 1/4 of the SE 1/4 of the SW 1/4 of Section 25, T55N, R34W.

Then go due west along the line which is the north boundary of the Michigan Bell Telephone Co. property and south boundary of the QDC property to the northwest corner of the Michigan Bell property. Bear southerly along the west boundary of the Michigan Bell tract approximately 40 feet to a point south of Quincy building No. 217. Then go due west, passing south of Quincy 217, to Pewabic Street.

Proceed due west to the north-south line dividing the SW 1/4 of the SW 1/4 of Section 25 from the SE 1/4 of the SW 1/4 of Section 25. Then north along this line to the east-west line dividing the W 1/2 of the SW 1/4 from the E 1/2 of the SW 1/4 of Section 25. Continue north approximately 150 feet, then due west to U.S. Highway 41 along an imaginary line which intersects the south edge of the highway scenic overlook.

Bear northwesterly across U.S. 41 following an imaginary line which runs parallel to but 150 feet south of the road to the Hancock water tank (Watertank Road). At the Hancock City boundary, proceed due north to the unmaintained right-of-way of former Q37 (Streetcar Track). Proceed northeast along the south side of former Q37 (Streetcar Track) to its junction with Q38, Karpenen Road. (See Map B)

From the junction, proceed 29 degrees northeast to Lake Annie Road (Township Road F15). Cross Lake Annie Road continuing along the same line another 150 feet. Then go southwesterly along an imaginary line running parallel to, but 150 feet northeast of, Lake Annie Road (Township Road F15) to the unmaintained right-of-way (former continuation of F23) which extends northeasterly to connect with Township Road F23 immediately east of Highway 41. (See Map B)

Continue northeasterly along the east side of the above-described right-of-way (former continuation of F23) to U.S. 41, then northeasterly along the east side of U.S. 41 to the junction of U.S. 41 and the east-west segment of Township Road F23. Bear southwesterly on the south side of Township Road F23 to Township Road F19, then northeasterly to the junction of Township Roads F19 and F39 and U.S. 41. At this point bear southeasterly at 90 degrees from Township Road F19 for 300 feet, then southwesterly along an imaginary line running parallel to Township Road F19 for 800 feet. Then southeasterly at 90 degrees to the previous course for approximately 800 feet to a point which lies 150 feet east of the Mesnard water tower. At this point, proceed southwesterly along an imaginary line running parallel to, but 150 feet southeast of, the Mesnard water tower road. Continue to Township Road F23.

Proceed westerly along the north side of Township Road F23 for approximately 150 feet to the junction with the Mesnard water tower road. At this point, proceed southwesterly along an imaginary line running at approximately 303 degrees to the junction of Township Road F20 and the unnamed road from Franklin to Newtown. (See Map B)

Proceed southeasterly along the south side of the Franklin-Newtown road to a point 150 feet northwest of the junction with the northern segment of the Newtown loop road. Then proceed east along an imaginary line running parallel to, but 150 feet north of, the northern segment of the Newtown loop road. Continue to a point 150 feet east of the southward bend in the Newtown loop road. Then go due south to a point 100 feet south of the Quincy and Torch Lake Railroad right-of-way.

Proceed westerly along an imaginary line running parallel to, but 100 feet south of, the Quincy and Torch Lake Railroad right-of-way to a point 50 feet east of the Franklin Incline. Then south along an imaginary line running parallel to, but 50 feet east of, the Franklin Incline to the point at which this line intersects an imaginary east-west line which passes through the northeast corner point of Quincy Lot 4, South Quincy Subdivision. (See Maps C & D).

Proceed west along this imaginary line to the northeast corner of Quincy Lot 4, South Quincy Subdivision. Continue westerly along the north boundaries of Quincy Lot 4, the Fire Hall tract, and the Kolehmainen property to the

northwest corner of the Kolehmainen property. Then proceed south along the west boundary of the Kohlemainen property and east boundary of the Michigan Technological University property to M-26, Royce Road. At M-26 (Royce Road) continue due south to the mean high water line of Portage Lake.

Then proceed westerly along the mean high water line of Portage Lake to the north-south property line between the Michigan Department of Transportation and QDC properties. Then go due north along that property line to the point of beginning.

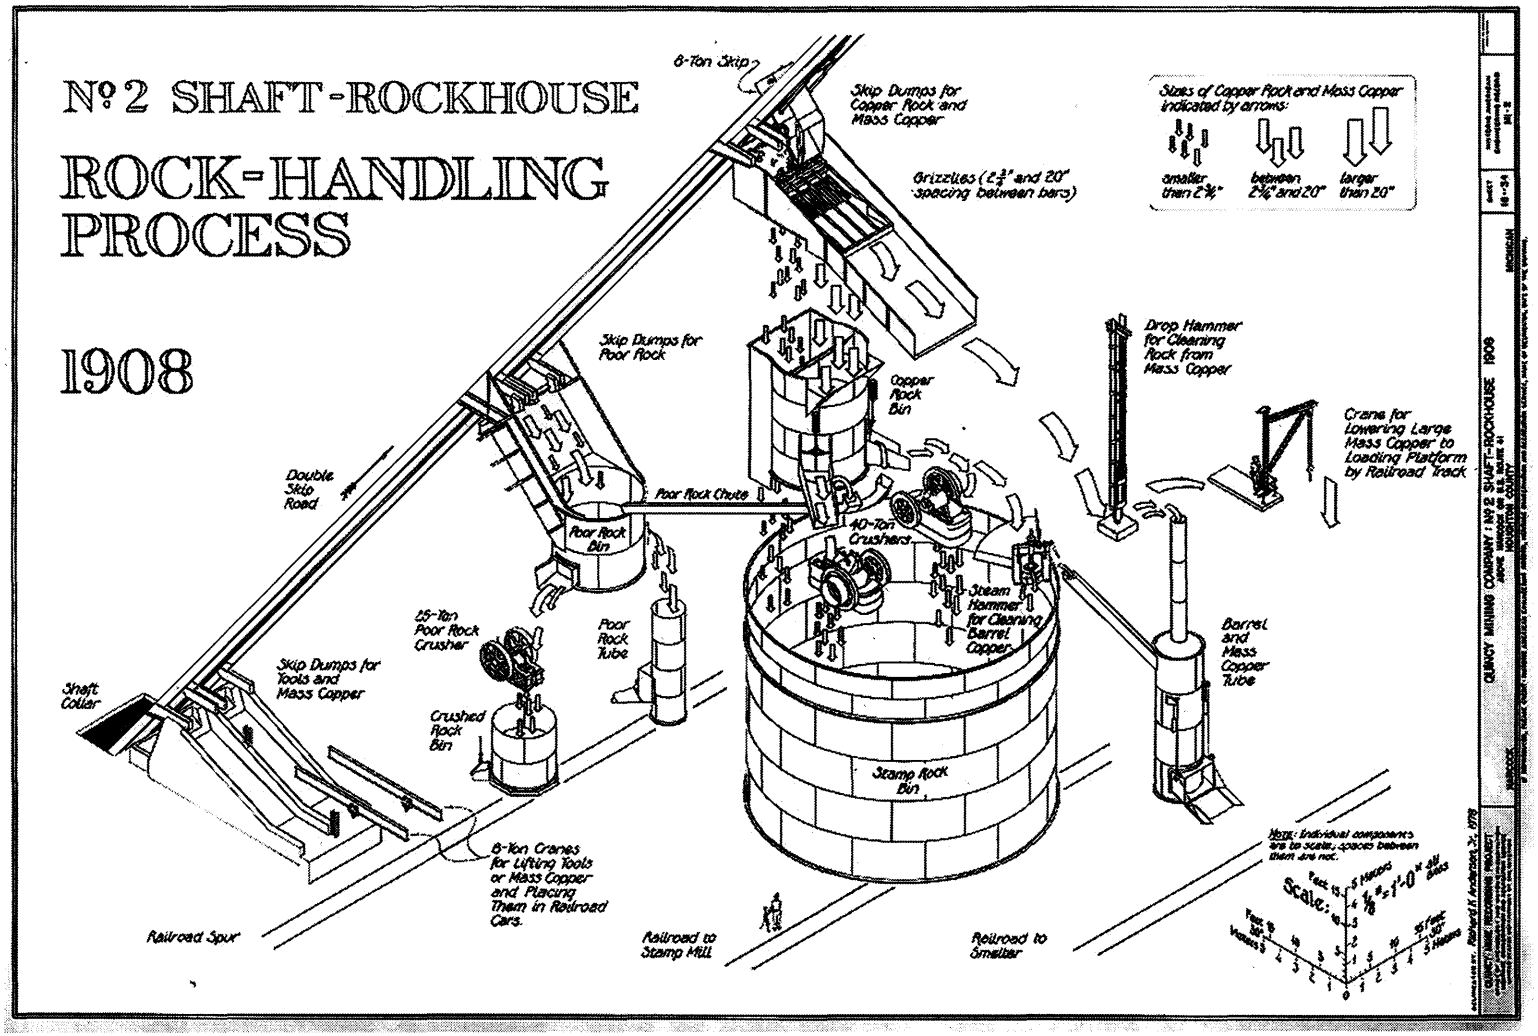
SHEET 2 - 34



Nº 2 SHAFT-ROCKHOUSE
ROCK-HANDLING PROCESS
1908
8-Ton Skip
Skip Dumps for Copper Rock and Mass Copper
Grizzlies (2½" and 20" spacing between bars)
Sizes of Copper Rock and Mass Copper indicated by arrows:
smaller than 2½"
between 2½" and 20"
larger than 20"
Skip Dumps for Poor Rock
Copper Rock Bin
Drop Hammer for Cleaning Rock from Mass Copper
Crane for Lowering Large Mass Copper to Loading Platform by Railroad Track
Double Skip Road
Poor Rock Chute
Poor Rock Bin
40-Ton Crushers
Steam Hammer for Cleaning Barrel Copper
25-Ton Poor Rock Crusher
Poor Rock Tube
Barrel and Mass Copper Tube
Skip Dumps for Tools and Mass Copper
Shaft Collar
Crushed Rock Bin
Stamp Rock Bin
6-Ton Cranes for Lifting Tools or Mass Copper and Placing Them in Railroad Cars.
Railroad Spur
Railroad to Stamp Mill
Railroad to Smelter
Note: Individual components are to scale; spaces between them are not.
Scale: 1/8" = 1'-0"
